Response to Seed Recipe Data Gaps

Andrew to Kevin and the MaziMeal team | November 4, 2026

Kevin, I recommend fixing the demo recipes first, then completing the 50-recipe set. Until quantities are reviewed, mark affected nutrition calculations as unavailable and exclude them from nutrient-based ranking. Your live-data audit is the baseline; my earlier local tests did not validate those live values.

Responses to the seven issues

1. Missing ingredients. Check the original recipe and instructions before adding anything. Calorie differences can flag a problem but cannot tell us which ingredient or amount is missing.

2. Unreliable quantities. Verify amounts, units, raw/cooked state, gram conversions and servings against the source. Keep unknown amounts blank, not zero. Re-pairing lists alone will not fix missing units; do not rescale quantities just to match published calories.

3. Missing rule tags. Expand reviewed tags for legumes, grains, seeds and dairy. Tags identify candidate rules; the optimizer still needs to check preparation, food combinations and other conditions. Keep rules marked do_not_automate out of automatic changes.

4. Ingredient order. Add separate fields for original ingredient and quantity positions. The current schema defines sequence_order as eating order, so we should resolve that meaning before using it for source order.

5. Unreviewed code definitions. Review the codes used by these 50 recipes first. I can prepare plain-language definitions and examples; Surabhi and Guy-Georges should confirm the engine interpretation. Keep review flags until each definition is approved.

6. Awkward ingredient names. Clean display names while keeping original text and stable IDs. Preserve distinctions such as lemon zest versus lemon juice, and check duplicates before merging records.

7. Quality flags. Track source, review status and missing nutrition coverage separately. Use "Published by Food.com" and "Calculated from ingredients" as labels. Default flags and fixed confidence scores do not prove accuracy; incomplete totals should remain unavailable.

My proposed handoff

Reviewed ingredient mappings and recipe quantities, documented tag definitions, repeatable database/import updates, and a before/after check for the 50 recipes. Each correction should retain its source and reviewer. I can estimate the remaining work after the first reviewed batch.

Input needed from the team

Kevin: confirm the demo recipes and API/UI behavior for unavailable nutrition.
Surabhi and Guy-Georges: agree tag meanings and rule conditions, then test integration.
Jessica or the recipe reviewer: resolve details the original sources cannot establish. User profiles remain deferred.
